Abstract

Background

Patients undergoing total hip arthroplasty (THA) are often advised to avoid driving for 6 weeks post operation. This is based on patients having to maintain post-operative hip precautions and studies investigating brake reaction time (BRT) following THA using conventional techniques. The aim of this study was to assess patients' ability to drive in the early post-operative period following micro-invasive THA by assessing BRT.

Methods

100 consecutive patients undergoing SuperPATH[®] THA in 2015 who drove automobiles pre-operatively were included in this prospective cohort study. BRT was measured pre-operatively and at day one or two post-operation using a driving simulator. A subset of 25 consecutive patients had repeat BRT testing at two weeks post-operation. Five BRT measures were taken at each time-point. Differences in the patient's mean and best BRT at each time point were assessed using the paired t-test.

15. To obtain CME credit for reading article(s) through Flagler Hospital's Internet Point of Care (iPOC) CME Activity, go to: <https://tinyurl.com/y9fxvult> or (<https://www.surveymonkey.com/r/NPH2773>) and answer all questions.

16. Repeat step 15 for every research topic made or article read.
